

Average Rate of Change & Secant Line

$$\text{Average Rate of Change} = \frac{f(x_2) - f(x_1)}{x_2 - x_1} = \frac{f(x_1) - f(x_2)}{x_1 - x_2}$$

Average Rate of Change is a single number indicating a rough amount computed for some measurable entity that changes or varies with time.

A **Secant Line**, also simply called a secant, is a line passing through two points of a curve.

Therefore **slope of a secant line** is the same as the Average Rate of Change.

Equation for Secant Line, if **A** indicates Average Rate of Change

while **f(x)** indicates horizontal axis value for secant line

computes as follows:

$$A = \frac{f(x) - f(x_1)}{x - x_1} \Rightarrow A(x - x_1) = f(x) - f(x_1) \Rightarrow A(x - x_1) + f(x_1) = f(x)$$

$$f(x) = Ax + (f(x_1) - Ax_1)$$

Example 1.

$$s = -\frac{29}{10}h - \frac{29}{10} \text{ average between } -2, 4$$

$$\Delta s = s(4) - s(-2) = -\frac{29}{10}(4) - \frac{29}{10} - \left(-\frac{29}{10}(-2) - \frac{29}{10}\right) = -\frac{87}{5}$$

$$\text{Secant Slope} = \tan(\theta) = \frac{s(4) - s(-2)}{4 - (-2)} = -\frac{29}{10}$$

$$\text{Average Rate of Change} = A = -\frac{29}{10}$$

$$\text{Secant Line: } s = -\frac{29}{10}h + \left(-\frac{29}{10}\right)$$

s could be temperature of a cup of tea and h time.

s could be speed of a car and h time.

s could be gasoline amount and h distance traveled.
